#### **ABSTRACT**

Skin diseases are more common than other diseases. Skin diseases can also be the result of fungal, bacterial, allergic or viral infections, etc. A skin condition can also change the feel or color of the skin. In general, skin diseases are chronic, contagious and can sometimes progress to skin cancer. Therefore, pore and skin diseases need to be detected early to limit their improvement and spread.

The analysis and treatment of a skin disease is time consuming and economically and physically expensive for the patient. In general, most normal people no longer recognize the type and extent of skin disease. Some skin diseases show signs and symptoms after several months, causing the disease to increase and develop. This is due to a lack of clinical information in the community. It can sometimes be difficult for a dermatologist (skin specialist) to diagnose a skin condition and may order a professional laboratory test to know the full type and extent of the condition, skin condition.

We propose an image processing-based method for the diagnosis of skin diseases. This method takes digital images or video images of the affected skin and then uses image analysis to determine the type of disease. Our proposed method is simple, fast, and requires no expensive equipment other than a camera and computer.

#### 1.INTRODUCTION:

#### **Project Overview:**

This study shows that CAD may also be a viable option in dermatology by presenting a novel method to sequentially combine accurate segmentation and classification models. Given an image of the skin, we decompose the image to normalize and extract high-level features. Using a neural network-based segmentation model to create a segmented map of the image, we then cluster sections of abnormal skin and pass this information to a classification model. We classify each cluster into different common skin diseases using an other neural network model. Our segmentation model achieves better performance compared to previous studies, and also achieves a near-perfect sensitivity score in unfavorable conditions.

#### **Purpose:**

Although computer-aided diagnosis(CAD) is used to improve the quality of diagnosis in various medica field ssuch as mammography and colonography, it is not used indermatology, where non invasive screening tests are performed only with the naked eye, and avoidable inaccuracies may exist. Our classification model is more accurate than a base line model trained without segmentation, while also being able to classify multiple diseases within a single image. This improved performance may be sufficient to use CAD in the field of dermatology.

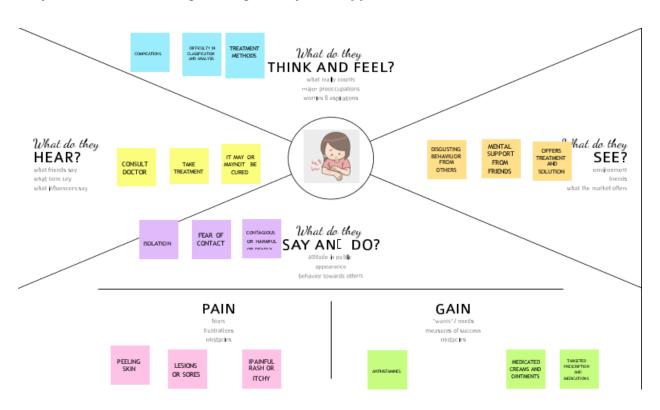

#### **2.LITERATURE SURVEY:**

#### **EXISTING PROBLEM:**

Skin diseases are the 4th common cause of skin burden worldwide. Robust and Automated system have been developed to lessen this burden and to help the patients to conduct the early assessment of the skin lesion. Mostly this system available in the literature only provide skin cancer classification. Treatments for skin are more effective and less disfiguring when found early and it is a challenging research due to similar characteristics of skin diseases. In this project we attempt to detect skin diseases. A novel system is presented in this research work for the diagnosis of the most common skin lesions (Melanocyticnevi,Melanoma, Benign keratosis-likelesions, Basalcellcarcinoma, Actinic keratoses,Vascular lesion, Dermatofibroma). The proposed approach is based on the pre-processing, Deep learning algorithm, training the model, validation and classification phase. Experiments were performed on 10010imagesand 93% accuracy is achieved for seven-class classification using Convolution Neural Networks(CNN) with the Keras Application

#### 3. Proposed Solution

CAD(ComputerAided Diagnosis) has been aviable option in dermatology by presenting an ovelmethod to sequentially combine accurate segmentation and classification models.

#### **Problem Solution fit:**

Skin disease canappearin virtually anypart of body and there is alackofdatarequired to formanassociation between the probability of a skindisease based on the bodypart. It is shown that current state-of-the-art CNN models can outperform models created by previous research, through proper data preprocessing, self-supervised learning, transfer learning, and special CNN architecture techniques. Furthermore, with accurate segmentation, we gain knowledge of the location of the disease, which is useful in the preprocessing of data used in classification, as it allows the CNN model to focus on the area of interest. Lastly, unlike previous studies, our method provides a solution to classify multiple diseases within a single image. With higher quality and a larger quantity of data, it will be viable to use state-of-the-art models to enable the use of CAD in the field of dermatology.

#### 4. Requirement Analysis:

#### **4.1 Functional Requirements:**

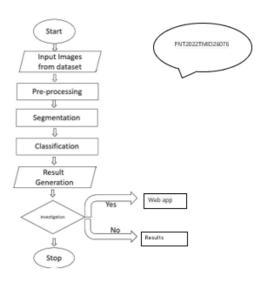

Temperature: If the temperature level exceeds theroom temperature then thealert messagewillbe sent using GSM, Pulse sensor to measure the pulseamplitude and width signals, GPS which is used to used to track the livelocation of the skin disease. GSM results in partial or whole-body exposures to electromagnetic field (EMF) communications, Webcamera collects medical images or images from WebCam are feed into the system, Raspberry pimicroprocessor in which all others ensors, GPS and GSM are integrated.

#### 4.2 Non-Functional Requirements :

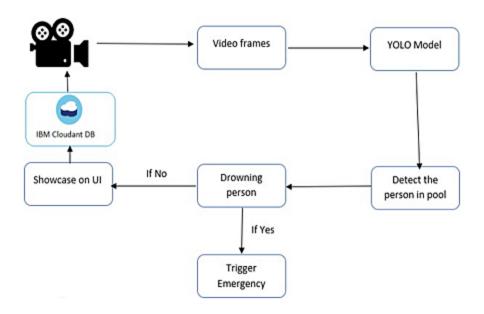

Usability, Security, Reliability, Performance, Availability, Scalability.

## 5. Project Design

## 5.1 Data Flow Diagram:

#### **5.2 Solutionand Technical Architecture :**

## **5.3** Components & Technologies:

S.No	Component	Description	Technology		
1.	User Interface	How user interacts with application e.g. Web UI, Mobile App, Chatbot etc.	HTML, CSS, JavaScript / Angular Js / React Js etc.		
2.	Application Logic-1	Logic for a process in the application	Java / Python		
3.	Application Logic-2	Logic for a process in the application	IBM Watson STT service		
4.	Application Logic-3	Logic for a process in the application IBM Watson Assistant	BM Watson Assistant		
5.	Database	Database Data Type, Configurations etc.	MySQL, NoSQL, etc.		
6.	Cloud Database	Database Service on Cloud IBM DB2, IBM Cloudant etc.	IBM DB2, IBM Cloudant etc.		
7.	File Storage	File storage requirements	IBM Block Storage or Other Storage Service or Local Filesystem		
8.	External API-1	Purpose of External API used in the application	IBM Weather API, etc.		
9.	External API-2	Purpose of External API used in the application	Aadhar API, etc.		
10.	Machine Learning Model	Purpose of Machine Learning Model	Object Recognition Model, etc.		

11.	Infrastructure (Server /	Application Deployment on Local	Local, Cloud Foundry,
	Cloud)	System / Cloud Local Server	Kubernetes, etc.
		Configuration: Cloud Server

## 7. Training the Model

We now have our dataset and the model, let's get them together:

model\_name = f"benign-vs-malignant\_{batch\_size}\_{optimizer}" tensorboard = tf keras\_callbacks.TensorBoard(log\_dir=os\_path\_ioin("logs", model\_name))

# saves model checkpoint whenever we reach better weights modelcheckpoint =

tf.keras.callbacks.ModelCheckpoint(model\_name + "\_{val\_loss:.3f}.h5", save\_best\_only=True, verbose=1)

history = m\_fit(train\_ds, validation\_data=valid\_ds, steps\_per\_epoch=n\_training\_samples // batch\_size, validation\_steps=n\_validation\_samples // batch\_size, verbose=1, epochs=100,

callbacks=[tensorboard\_modelcheckpoint])

Here is a part of the output during training:

Train for 31 steps, validate for 2 steps

```
Epoch 1/100
Epoch 00001: val loss improved from inf to 0.49703, saving model to benign-vs-malignant 64 rmsprop 0.497 h5
val_accuracy: 0.8125
SNIPED..>
Epoch 27/100
Epoch 00027: val_loss improved from 0.40253 to 0.38991, saving model to benign-vs-malignant_64_rmsprop_0.390.h5
31/31 [======] - 21s 691ms/step - loss: 0.3025

    accuracy: 0.8684 - val loss; 0.3899 - val accuracy; 0.8359

SNIPED..>
Epoch 41/100
Epoch 00041: val_loss did not improve from 0.38991
31/31 [=============] - 21s 690ms/step - loss: 0.2829

    accuracy: 0.8790 - val_loss: 0.3948 - val_accuracy: 0.8281

Epoch 42/100
Epoch 00042: val loss did not improve from 0.38991
val_accuracy: 0.8047
```

#### **Model Evaluation:**

First, let's load ourtest set, just like previously:

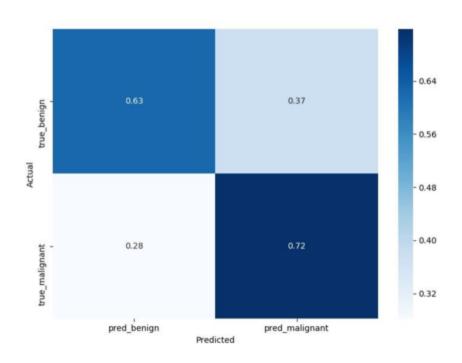

```
# evaluation # load
testing set
test_metadata_filename = "test.csv" df_test =
pd_read_csx(test_metadata_filename) n_testing_samples =
len(df_test)
print("Number of testing samples:", n_testing_samples)
test_ds = tf_data_Dataset_from_tensor_slices((df_test["filepath"], df_test["label"]))
def prepare, for testing(ds, cache=True, shuffle, buffer_size=1000):
if cache: if isinstance(cache, str): ds = ds.cache(cache)
isinstance(cache, str): ds = ds.cache(cache)
     else :
        ds = ds cache ()
  ds = ds_shuffle__(buffer_size = shuffle_buffer_size
  return ds
test_ds = test_ds . map(process_path )
test_ds = prepare_for_testing (test_ds , cache ="test - cached - data" )
```

#### Results:

The below function does that:

```
def get_predictions____
                        (threshold
                                      =None):
  10000
  Returns predictions for binary classification given 'threshold'
  For instance, if threshold is 0.3, then it'll output 1 (malignant)
for that sample if
  the probability of 1 is 30% or more (instead of 50%)
  v_pred = m predict (X_test )
  if not threshold :
     threshold = 0.5
  result = np. zeros (( n testing samples
                                               ,))
  for i in range (n_testing_samples
     # test melanoma probability
     if y pred [i][0] >= threshold
       result [i] = 1
     # else, it's 0 (benign)
  return result
threshold
            = 0.23
# get predictions with 23% threshold
# which means if the model is 23% sure or more that is malignant,
# it's assigned as malignant, otherwise it's benign
y pred = get predictions (threshold
```

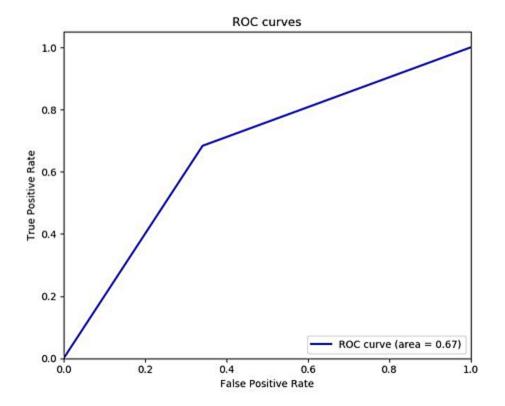

Now let's draw our confusion matrix and interpret it:

```
def plot roc auc (v. true, v. pred):
    This function plots the ROC curves and provides the scores.
     .....
    # prepare for figure
    plt__ figure ()
    for__ tor , _ = roc_curve (v_true , v_pred )
     # obtain ROC AUC
    roc_auc = auc_fpr , tpr )
    # print score
    print __ f"ROC_AUC: { roc_auc : .3 f } ")
    # plot ROC curve
     plt__plot (_fpr , tpr , color ="blue" , lw=2,
                  label ='ROC curve (area = {f:.2f})' . format (_d=1,
f = roc_auc ))
     plt___xlim_ ([ 0.0__ 1.0 ])
    plt . vlim ([ 0.0 1.05 ])
     plt__xlabel__(_'False Positive Rate' )
     plt . ylabel ('True Positive Rate' )
    plt . title __('ROC curves' )
    plt__legend (loc ="lower right" )
     glt . show()
plot_roc_auc__(v_test , v_pred )
```

#### Output:

ROC AUC: 0.671

**ROCAUC: 0.671** 

#### 9. Advantages and Disadvantages:

#### 9.1 Advantages:

Instant Response, improves prediction of Skin Disease, no referral needed, Saves Money and Time, and Confidential Advice.

#### 9.2 Disadvantages:

**Network Connectivity and Accuracy** 

10. Conclusion:

We have shown that even without a large dataset and high-quality images, it is

possible to achieve sufficient accuracy rates. Inaddition, we have shown that current state-of-

the-art CNN models can outperform models created by previous research, through proper data

pre-processing, self-supervised learning, transfer learning, and special CNN architecture techniques.

Furthermore, with accurate segmentation, we gain knowledge of the location of the disease, which is

useful in the pre-processing of data used in classification, as it allows the CNN model to focus on the area

of interest. Lastly, unlike previous studies, our method provides a solution to classify multiple diseases

within a single image. With higher quality and a larger quantity of data, it will be viable to use state-of-

the-art models to enable the use of CAD in the field of dermatology.

11. FutureScope:

This implementation of the Structural Co-Occurrence matrices for feature extraction in the skin diseases

classification and the pre-processing techniques are handled by using the Median filter, this filter helps to

remove the salt and pepper noise in the image processing; thus, it enhances the quality of the images,

and normally, the skin diseases are considered as the risk factor in all over the world. Ourproposed

approach provides 97% of the classification of the accuracy results while another existing model such as

FFT + SCM gives 80%, SVM + SCM gives 83%, KNN + SCM gives 85%, and SCM + CNN gives 82%. Future

work is dependent on the increased support vector machine's accuracy in classifying skin illnesses, and

SCM is used to manage the feature extractiontechnique.
